Bidiagonal Decomposition and LSQR

Block Bidiagonalization Methods

Multiple Right-Hand Sides in LS and TLS

Rank Deficient Blocks and Deflation

Summary
In 1965 Golub and Kahan gave two algorithms for computing a bidiagonal decomposition (BD)

\[ A = U \begin{pmatrix} L \\ 0 \end{pmatrix} V^T \in \mathbb{R}^{m \times n}, \]

where \( B \) is lower bidiagonal,

\[ B = \begin{pmatrix} \alpha_1 & & & & \\ \beta_2 & \alpha_2 & & & \\ & \beta_3 & \ddots & & \\ & & \ddots & \alpha_n & \\ & & & \beta_{n+1} \end{pmatrix} \in \mathbb{R}^{(n+1) \times n}, \]

and \( U \) and \( V \) are square orthogonal matrices. Given \( u_1 = Q_1 e_1 \), the decomposition is uniquely determined if \( \alpha_k \beta_{k+1} \neq 0, \ k = 1 : n, \)
The Bidiagonal Decomposition

The Householder Algorithm

For given Householder matrix $Q_1$, set $A_0 = Q_1 A$, and apply Householder transformations alternately from right and left:

$$A_k = Q_{k+1}(A_{k-1}P_k), \quad k = 1, 2, \ldots.$$ 

$P_k$ zeros $n - k$ elements in $k$th row; 
$Q_{k+1}$ zeros $m - k - 1$ elements in the $k$th column.

If $Q_1$ is chosen so that $Q_1 b = \beta_1 e_1$, then

$$U^T (b \ AV) = \begin{pmatrix} \beta_1 e_1 & B \\ 0 & 0 \end{pmatrix},$$

where $B$ is lower bidiagonal and

$$U = Q_1 Q_2 \cdots Q_{n+1}, \quad V = P_1 P_2 \cdots P_{n-1}.$$
The Bidiagonal Decomposition

Lanczos algorithm

In the Lanczos process, successive columns of

\[ U = (u_1, u_2, \ldots, u_{n+1}), \quad V = (v_1, v_2, \ldots, v_n), \]

with \( \beta_1 u_1 = b \), \( \beta_1 = \|b\|_2 \), are generated recursively.

Equating columns in

\[ A^T U = VB^T \quad \text{and} \quad AV = UB, \]

gives the coupled two-term recurrence relations (\( v_0 \equiv 0 \)):

\[ \alpha_k v_k = A^T u_k - \beta_k v_{k-1}, \]
\[ \beta_{k+1} u_{k+1} = Av_k - \alpha_k u_k, \quad k = 1 : n. \]

Here \( \alpha_k \) and \( \beta_{k+1} \) are determined by the condition

\[ \|v_k\|_2 = \|u_k\|_2 = 1. \]
The Bidiagonal Decomposition

Since the BD is unique, \textit{both algorithms generate the same decomposition in exact arithmetic.}

From the Lanczos recurrences it follows that

\[ U_k = (u_1, \ldots, u_k) \text{ and } V_k = (v_1, \ldots, v_k), \]

form orthonormal bases for the left and right Krylov subspaces

\[ \mathcal{K}_k(AA^T, u_1) = \text{span}\left[ b, AA^T b, \ldots, (AA^T)^{k-1} b \right], \]

\[ \mathcal{K}_k(A^T A, v_1) = \text{span}\left[ A^T b, \ldots, (A^T A)^{k-1} A^T b \right]. \]

If either \( \alpha_k = 0 \) or \( \beta_{k+1} = 0 \), the process terminates. Then the maximal dimensioned Krylov space has been reached.
The LSQR algorithm (Paige and Saunders 1982) is a Krylov subspace method for the LS problem

$$\min_x \| b - Ax \|_2.$$ 

After $k$ steps, one seeks an approximate solution

$$x_k = V_k y_k \in K_k(A^T A, A^T b).$$

From the recurrence formulas it follows that $A V_k = U_{k+1} B_k$. Thus

$$b - AV_k y_k = U_{k+1} (\beta_1 e_1 - B_k y_k),$$

where $B_k$ is lower bidiagonal. By the orthogonality of $U_{k+1}$ the optimal $y_k$ is obtained by solving a bidiagonal subproblem

$$\min_y \| \beta_1 e_1 - B_k y \|_2,$$
Least Squares and LSQR

This is solved using Givens rotations to transform $B_k$ into upper bidiagonal form

$$G(\beta_1 e_1 \mid B_k) = \begin{pmatrix} -f_k & R_k \\ \phi_{k+1} & 0 \end{pmatrix}.$$ 

giving

$$x_k = VR_k^{-1} f_k, \quad \| b - Ax_k \|_2 = |\bar{\phi}_{k+1}|.$$ 

Then $x_k, k = 1, 2, 3, \ldots$ gives approximations on a nested sequence of Krylov subspaces. Often superior to truncated SVD.

LSQR uses the Lanczos recursion and interleaves the solution of the LS subproblems. A Householder implementation could be used for dense $A$. 
Bidiagonalization can also be used for total least squares (TLS) problems. Here the error function to be minimized is

\[
\frac{\| \mathbf{b} - \mathbf{A} \mathbf{x}_k \|_2^2}{\| \mathbf{x}_k \|_2^2 + 1} = \frac{\| \beta_1 \mathbf{e}_1 - \mathbf{B}_k \mathbf{y}_k \|_2^2}{\| \mathbf{y}_k \|_2^2 + 1}.
\]

The solution of the lower bidiagonal TLS subproblems are obtained from the SVD of matrix

\[
\begin{pmatrix}
\beta_1 \mathbf{e}_1 & \mathbf{B}_k
\end{pmatrix}, \quad k = 1, 2, 3, \ldots.
\]

Partial least squares (PLS) is widely used in data analysis and statistics. PLS is mathematically equivalent to LSQR but differently implemented. The predictive variables tend to be many and are often highly correlated.

Bidiagonal Decomposition and LSQR

Block Bidiagonalization Methods

Multiple Right-Hand Sides in LS and TLS

Rank Deficient Blocks and Deflation

Summary
Let $Q_1$ be a given $m \times m$ orthogonal matrix and set

$$U_1 = Q_1 \begin{pmatrix} I_p \\ 0 \end{pmatrix} \in \mathbb{R}^{m \times p}.$$

Next form $Q_1^T A$ and compute the LQ factorization of its first $p$ rows

$$(I_p \ 0)(Q_1^T A)P_1 = (L_1 \ 0),$$

where $L_1$ is lower triangular.

Proceed by alternately performing QR factorizations of blocks of $p$ columns and LQ factorizations of blocks of $p$ rows.
After \( k \) steps we have computed a block bidiagonal matrix

\[
T_k = \begin{pmatrix}
L_1 & & & \\
& R_2 & L_2 & \\
& & \ddots & \ddots \\
& R_k & & L_k \\
& & & R_{k+1}
\end{pmatrix} \in \mathbb{R}^{(k+1)p \times kp},
\]

and two block matrices with orthogonal columns

\[(U_1, U_2, \ldots, U_{k+1}) = Q_{k+1} \cdots Q_2 Q_1 \begin{pmatrix} I_{(k+1)p} \\ 0 \end{pmatrix},\]

\[(V_1, V_2, \ldots, V_{k}) = P_k \cdots P_2 P_1 \begin{pmatrix} I_{kp} \\ 0 \end{pmatrix}.\]

The matrix \( T_k \) is a banded lower triangular matrix with \((p + 1)\) nonzero diagonals.
The Householder algorithm gives a constructive proof of the existence of such a block bidiagonal decomposition.

If the LQ and QR factorizations have full rank then the decomposition is uniquely determined by $U_1$.

To derive a block Lanczos algorithm we use the identities

\[
A(V_1 \ V_2 \cdots \ V_n) \ = \ (U_1 \ U_2 \cdots \ U_{n+1}) T_n \\
A^T(U_1 \ U_2 \cdots \ U_{n+1}) \ = \ (V_1 \ V_2 \cdots \ V_n) T_n^T.
\]

Start by forming $Z_1 = A^T U_1$ and compute its thin QR factorization

\[
Z_1 = V_1 L_1^T.
\]
For $k = 1 : n$, we then do: Compute the residuals

$$W_k = AV_k - U_k L_k \in \mathbb{R}^{m \times p},$$

and compute the QR factorization $W_k = U_{k+1} R_{k+1}$. Compute the residuals

$$Z_{k+1} = A^T U_{k+1} - V_k R_{k+1}^T \in \mathbb{R}^{n \times p},$$

and compute the QR factorization $Z_{k+1} = V_{k+1} L_{k+1}^T$.

Householder QR factorizations can be used to guarantee orthogonality within each block $U_k$ and $V_k$. 
The **block Lanczos bidiagonalization** was given by Golub, Luk, and Overton in 1981.

From the Lanczos recurrence relations it follows by induction that for \( k = 1, 2, 3, \ldots \), the block algorithm generates orthogonal bases for the Krylov spaces

\[
\text{span}(U_1, \ldots, U_k) = \mathcal{K}_k(AA^T, U_1),
\]
\[
\text{span}(V_1, \ldots, V_k) = \mathcal{K}_k(A^TA, A^TU_1),
\]

The process can be continued as long as the residual matrices have full column rank. Rank deficiency will be considered later.
Outline

Bidiagonal Decomposition and LSQR

Block Bidiagonalization Methods

Multiple Right-Hand Sides in LS and TLS

Rank Deficient Blocks and Deflation

Summary
In many applications one needs to solve least squares problems with *multiple right-hand sides* \( B = (b_1, \ldots, b_p) \).

\[
B = (b_1, \ldots, b_d), \quad d \geq 2.
\]

There are two possible approaches;

- Select a *seed* right-hand side and use the Krylov subspace generated to start up the solution of the second, etc.
- Use a *block* Krylov solver where all right-hand sides are treated simultaneously.

Block Krylov methods:

- use a much larger search space from the start
- introduce matrix–matrix multiplies into the algorithm.
A natural generalization of LSQR is to compute a sequence of approximate solutions of the form

$$X_k = V_k Y_k, \quad k = 1, 2, 3, \ldots,$$

are determined. That is, $X_k$ is restricted to lie in a Krylov subspace $\mathcal{K}_k(A^T A, A^T B)$. It follows that

$$B - AX_k = B - AV_k Y_k = U_{k+1}(R_1 E_1 - T_k Y_k).$$

Using the orthogonality of the columns of $U_{k+1}$ gives

$$\|B - AX_k\|_F = \|R_1 E_1 - T_k Y_k\|_F.$$
Hence $\| B - AX_k \|_F$ is minimized for $X_k \in \mathcal{R}(V_k)$ by taking $X_k = V_k Y_k$, where $Y_k$ solves

$$\min_{Y_k} \| R_1 E_1 - T_k Y_k \|_F.$$ 

The approximations $X_k$ are the optimal solutions on the nested sequence of block Krylov subspaces.

$$\mathcal{K}_k(A^T A, A^T B), \quad k = 1, 2, 3, \ldots.$$ 

The block bidiagonal LS subproblems are solved by using orthogonal transformations to bring the lower triangular banded matrix $T_k$ into upper triangular banded form.
As in LSQR the solution can be interleaved with the block bidiagonalization. For example, \((p = 2)\)

\[
\begin{pmatrix}
\times & \times & \times & \times & \times & \times & \times & \times \\
\times & \times & \times & \times & \times & \times & \times & \times \\
\times & \times & \times & \times & \times & \times & \times & \times \\
\times & \times & \times & \times & \times & \times & \times & \times \\
\end{pmatrix}
= \begin{pmatrix} C_1 & R_X & S_1 \\ C_2 & 0 & S_2 \end{pmatrix}.
\]

At this step the approximate solution to \(\min \|AX - B\|_F\), is

\[
X = V_k(R_X^{-1} C_1), \quad \|B - AX\|_F = \|C_2\|_f.
\]
The block algorithm can be used also for **TLS problems with multiple right-hand sides** which is

\[
\min_{E, F} \| (F \quad E) \|_F, \quad (A + E)X = B + F,
\]

This cannot, as the LS problem, be reduced to \( p \) separate problems.

Using the orthogonal invariance, the error function to be minimized is

\[
\frac{\| B - AX \|^2_F}{\| X \|^2_F + 1} = \frac{\| R_1 E_1 - TY \|^2_F}{\| Y \|^2_F + 1}.
\]
The TLS solution can be expressed in terms of the SVD

$$(B \ A) = (U_1 \ U_2) \begin{pmatrix} \Sigma_1 \\ \Sigma_2 \end{pmatrix} \begin{pmatrix} V_1^T \\ V_2^T \end{pmatrix},$$

where $\Sigma_1 = \text{diag}(\sigma_1, \ldots, \sigma_n)$.

The solution of the lower triangular block bidiagonal TLS problem can be constructed from the SVD of the block bidiagonal matrix.
Outline

Bidiagonal Decomposition and LSQR

Block Bidiagonalization Methods

Multiple Right-Hand Sides in LS and TLS

Rank Deficient Blocks and Deflation

Summary
When rank deficient blocks occur the bidiagonalization must be modified. For example \((p = 1)\), at a particular step

\[
Q_3 Q_2 Q_1 (b, AP_1 P_2) = \begin{pmatrix}
\beta_1 & \alpha_1 \\
\beta_2 & \alpha_2 \\
\beta_3 & \times & \otimes & \otimes \\
\times & \times & \times \\
\otimes & \times & \times \\
\otimes & \times & \times \\
\otimes & \times & \times 
\end{pmatrix},
\]

If \(\alpha_3 = 0\) or \(\beta_4 = 0\), the reduced matrix has into block diagonal form. Then the LS problem decomposes and the bidiagonalization can be terminated.
Rank Deficient Blocks and Deflation

If \( \alpha_k = 0 \), then

\[
U_k^T(b, AV_k) = \begin{pmatrix} \beta_1 e_1 & T_k & 0 \\ 0 & 0 & A_k \end{pmatrix}
\]

and the problem is reduced to

\[
\min_y \| \beta_1 e_1 - T_k y \|_2.
\]

Then the right Krylov vectors

\[
A^T b, (A^T A)A^T b, \ldots, (A^T A)^{k-1} A^T b
\]

are linearly dependent.
Rank Deficient Blocks and Deflation

If \( \beta_{k+1} = 0 \), then

\[
U_{k+1}^T (b, AV_k) = \begin{pmatrix}
\beta_1 e_1 & \tilde{T}_k & 0 \\
0 & 0 & A_k
\end{pmatrix}
\]

where \( \tilde{T}_k = (T_k \alpha_k e_k) \) is square. Then the original system is consistent and the solution satisfies

\[
\tilde{T}_k y = \beta_1 e_1.
\]

Then the left Krylov vectors

\[
b, (AA^T)b, \ldots, (AA^T)^k b
\]

are linearly dependent.
From well known properties of tridiagonal matrices it follows:

• The matrix $T_k$ has full column rank and its singular values are simple.

• The right-hand side $\beta e_1$ has nonzero components along each left singular vector of $T_k$.

Paige and Strakoš call this a core subproblem and shows that it is minimally dimensioned.

If we scale $b := \gamma b$, then only $\beta_1$ changes. Thus, we have a core subproblem for any weighted TLS problem.

$$\min \| (\gamma r, E) \|_F \text{ s.t. } (A + E)x = b + r.$$
How do we proceed in the block algorithm if a rank deficient block occurs in an LQ or QR factorization?

The triangular factor then typically has the form ($p = 4$ and $r = \text{rank}(R_k) = 3$):

\[
R_k = \begin{pmatrix}
\times & \times & \times & \times \\
0 & \times & \times & \\
0 & & \times & \\
0 & & & \\
\end{pmatrix} \in \mathbb{R}^{r \times p}.
\]

(Recall that the factorizations are performed without pivoting).

All following elements in this diagonal of $T_k$ will be zero. The **bandwidth** and **block size** are reduced by one.
Example $p = 2$: Assume that the first element in the diagonal of the block $R_2$ becomes zero.

If a diagonal element (say in $L_3$) becomes zero the problem decomposes.

In general, the reduction can be terminated when the bandwidth has been reduced $p$ times.
Deflation is related to linear dependencies in the associated Krylov subspaces:

If \((AA^T)^k b_j\) is linearly dependent on previous vectors, then all left and right Krylov vectors of the form

\[
(AA^T)^p b_j, \quad (A^T A)^p A^T b_j, \quad p \geq k,
\]

should be removed.

If \((A^T A)^k A^T b_j\) is linearly dependent on previous vectors, then all vectors of the form

\[
(A^T A)^p A^T b_j, \quad (AA^T)^{p+1} b_j, \quad p \geq k,
\]

should be removed.

When the reduction terminates when both left and right Krylov subspaces have reached their maximal dimensions.
The block Lanczos algorithm is modified similarly when a rank deficient block occurs. Recall the block Lanczos recurrence:

For $k = 1 : n$,

$$V_k L_k^T = A^T U_k - V_{k-1} R_k^T,$$

$$U_{k+1} R_{k+1} = A V_k - U_k L_k.$$

Suppose the first rank deficient block is

$$L_k \in \mathbb{R}^{p \times r}, \quad r < p.$$

Then $V_k$ is $n \times r$, i.e. only $r < p$ vectors are determined. In the next step

$$AV_k - U_k L_k \in \mathbb{R}^{m \times r}.$$

Recurrence still works! Block size has been reduced to $r$.

Summary
• We have emphasized the similarity and (mathematical) equivalence of the Householder and Lanczos algorithms for block bidiagonalization.

For dense problems in data analysis and statistics the Householder algorithm should be used because of its backward stability. Today quite large dense problems can be handled in seconds on a desktop computer!
