Weak solutions of the Poisson equation

Now we are ready to demonstrate the usefulness of Sobolev spaces in the simplest situation, namely, we prove the existence of weak solutions of the Poisson equation.

Let $U$ be a bounded open subset of $\mathbb{R}^n$ and let us consider the Dirichlet problem for the Poisson equation:

$$\Delta u(x) = f(x), \quad x \in U$$
$$u(x) = 0, \quad x \in \partial U.$$

Since we are interested in the zero boundary condition, it is reasonable to consider $C_0^\infty(U)$ as the class of test functions. Let $u$ be the classical solution of the above Dirichlet problem. Then multiplying the Poisson equation by an arbitrary test function $v \in C_0^\infty(U)$ and integrating the obtained equality by parts yields

$$- \int_U f \varphi \, dx = \int_U \nabla u \cdot \nabla v \, dx$$

(1)

The following remarks are appropriate to mention here:

(a) The latter equality may also be interpreted for any function $u$ of a larger class $H_0^{1,2}(U)$.
(b) A bilinear form

$$(u, v) := \int_U \nabla u \cdot \nabla v \, dx$$

in the left hand side looks like a scalar product.
(c) The identity (1) can be interpreted now as equation on a linear functional

$$F(v) := - \int_U f v \, dx$$

(2)

and the scalar product $(u, v)$ that resembles the Riesz representation theorem
(d) If $f \in L^2(U)$, the linear functional $F(v)$ defined above is bounded in $L^2(U)$-norm for subspace $C_0^\infty(U)$ and moreover, we have

$$|F(v)| \leq \left( \int_U f^2 \, dx \right)^{1/2} \left( \int_U v^2 \, dx \right)^{1/2} = \|f\|_{L^2} \|v\|_{L^2} \leq \|f\|_{L^2} \|v\|_{H_0^{1,2}}$$

that is $F(v)$ extends (by Hahn-Banach theorem) to a bounded functional in $H_0^{1,2}(U)$.

We return to the scalar product defined above. In fact, the bilinear form

$$(u, v) := \int_U \nabla u \cdot \nabla v \, dx$$

is well-defined in the whole $H_0^{1,2}(U)$, symmetric and positive there (notice that $|u|_1 = 0$ yields $u \equiv const$, which implies, by the zero boundary condition, $u \equiv 0$). Denote by $|u|_1 = \sqrt{(u, u)}$ the associated norm.
Hence we obtain a **weak formulation** of (1): given a function \( f \in L^2(U) \), any classical solution \( u \) to the Poisson equation with zero boundary condition is a solution of the following problem

\[
(u, v) = F(v), \quad \forall \ v \in C_0^\infty(U),
\]  

where \( F \) is defined by (2). The following definition is then natural.

**Definition.** A function \( u \in H_0^{1,2}(U) \) which solves (3) is called a weak solution to the Poisson equation with zero boundary conditions.

In order to threat the existence of a weak solution we show that the new scalar product generates the same metric (and topological) structure in \( H_0^{1,2}(U) \).

**Poincare’s inequality**

**Theorem** (Poincare’s inequality). If \( U \) is a bounded open subset of \( \mathbb{R}^n \) then there exists a constant \( C = C(U) > 0 \) such that

\[
\int_U |\nabla v|^2(x) \, dx \geq C \int_U v^2(x) \, dx
\]

for all \( v \in C_0^1(U) \). Moreover, the inequality holds for any function in \( H_0^{1,2}(U) \)

Denote by the same letter \( v \) the function obtained by extending \( v \) by zero outside of \( U \). Let \( M \) be large enough such that the support of \( v \) is contained in the cube \( Q = \{x: |x_k| \leq M\} \).

Notice that \( \frac{\partial}{\partial x_k} x_k = 1 \), hence integrating by parts we find

\[
\int_U v^2(x) \, dx = \int_Q v^2 \frac{\partial x_k}{\partial x_k} \, dx = -2 \int_Q x_k v v'_k \, dx \leq 2M \int_Q |v v'_k| \, dx
\]

Applying Cauchy inequality \( \left( \int_Q |v v'_k| \, dx \right)^2 \leq \int_Q v^2 \, dx \int_Q v'_k \, dx \) we obtain

\[
\frac{1}{4M^2} \int_U v^2 \, dx = \frac{1}{4M^2} \int_Q v^2 \, dx \leq \int_Q v'_k \, dx \leq \frac{1}{4M^2} \int_U |\nabla v|^2 \, dx
\]

and the desired property follows.

**Remark 1.** The question on the optimal constant in the Poincare inequality has many relations to other problems in mathematics and mathematical physics. For instance, if one think of \( U \) as a membrane then the best constant \( \sqrt{C} \) in the Poincare inequality is exactly the fundamental frequency \( \lambda_1 \) (sometimes is called also the fundamental tone) of \( U \). If \( U = [0, L] \) is the one-dimensional interval then \( \lambda_1 = \pi/L \). Besides the fundamental tone, one distinguish also a series of higher “tones” (see the first picture below). The second picture shows the oscillating two-dimensional membrane corresponding to the \( 7^{th} \) tone \( v = \sin 2x_1 \sin 4x_2 \) in the rectangle \( U = [0,1] \times [0,1] \).
Remark 2. The above Poincare inequality is a partial case of a more general relation (the so-called Poincare-Friedrichs inequality)

\[
\int_U |\nabla v|^p(x) \, dx \geq C_p \int_U v^p(x) \, dx, \quad \forall v \in C^1_0(U)
\]

which can be proved by the same method.

Corollary 1. If \( U \) is a bounded open subset of \( \mathbb{R}^n \) then there exists a constant \( C = C(U) > 0 \) such that for any \( v \in H_{0}^{1,2}(U) \)

\[
\|v\|_{H^{1,2}} \leq C_1 \|\nabla v\|_{L^2}
\]

Indeed, for any \( v \in H_{0}^{1,2}(U) \) Poincare’s inequality yields

\[
\|v\|_{H^{1,2}}^2 = \int_U (|\nabla v|^2 + |v|^2) \, dx \leq (1 + C(U)) \int_U |\nabla v|^2 \, dx = |v|^2_1
\]

Corollary 2 (Existence and uniqueness of the weak solution). For any \( f \in L^2(U) \) there is a unique function \( u \in H_{0}^{1,2}(U) \) which solves (3).

By Corollary 1 we have \( \|v\|_{H^{1,2}} \leq C_1 \|\nabla v\|_{L^2} \) and, in the other direction,

\[
|v|^2_1 = \int_U |\nabla v|^2 \, dx \leq \int_U (|\nabla v|^2 + |v|^2) \, dx = \|v\|_{H^{1,2}}^2.
\]

It follows that \( |u|_1 \) and \( \|u\|_{H^{1,2}} \) are equivalent norms.

On the other hand, \( F \) defined by (2) is a bounded linear functional in \( H_{0}^{1,2}(U) \). Hence, applying the Riesz representation theorem to the new scalar product \((u, v)\) we immediately conclude that there is a unique function \( u \in H_{0}^{1,2}(U) \) such that

\[
F(v) = (u, v), \quad \forall v \in H_{0}^{1,2}(U)
\]

That is \( u \) is a weak solution to the Dirichlet problem formulated above. ■
Existence of weak solutions for general elliptic equations

The method described above can be applied also to the Dirichlet problem for more general elliptic equations. Consider a differential operator in divergence form

$$Lu = \sum_{i,j=1}^{n} \frac{\partial}{\partial x_i} \left( a_{ij}(x) \frac{\partial u}{\partial x_j} \right) + c(x)u(x).$$

where \(a_{ij}(x) = a_{ji}(x), \ a_{ij}(x) \in C^\infty(\bar{U}), \ c(x) \in C^\infty(\bar{U})\) and \(a_{ij}(x)\) satisfying the (uniform) ellipticity condition: there is a constant \(\alpha > 0\) such that for any \(\xi \in \mathbb{R}^n\)

$$\sum_{i,j=1}^{n} a_{ij}(x) \xi_i \xi_j \geq \alpha \|\xi\|^2.$$

Starting from a smooth solution and integrating by parts, we see that the natural definition of a weak solution is the following.

**Definition.** A function \(u \in H^{1,2}_0(U)\) which solves (3) is called a weak solution to \(Lu = 0\) with zero boundary conditions if

$$- \int_{\Omega} f v \, dx = \int_{\Omega} \left( \sum_{i,j=1}^{n} a_{ij}(x) \frac{\partial u}{\partial x_i} \frac{\partial v}{\partial x_j} - c(x)uv \right) \, dx, \quad \forall v \in C^\infty_0(U). \tag{4}$$

It is then convenient to restate the condition for a weak solution as follows:

$$F(v) = B(u,v), \quad v \in C^\infty_0(U), \tag{5}$$

where \(F(\cdot)\) is defined as before by formula (2) and the new bilinear form is given by

$$B(u,v) = \int_{\Omega} \left( \sum_{i,j=1}^{n} a_{ij}(x) \frac{\partial u}{\partial x_i} \frac{\partial v}{\partial x_j} - c(x)uv \right) \, dx.$$

The existence of a weak solution will follow immediately if we show that \(B(u,v)\) is a scalar product whose associated norm is equivalent to the standard norm in \(H^{1,2}_0(U)\). So we need to investigate under which conditions \(B(u,v)\) meets these criteria.

First we notice that \(B(u,v)\) is symmetric by our assumption on the coefficients \(a_{ij}(x)\). Next, by using of the ellipticity condition we obtain the following lower estimate:

$$B(u,u) \geq \int_{\Omega} \left( \alpha \|\nabla u\|^2 - \gamma u^2 \right) \, dx \geq \alpha \|\nabla u\|^2_{L^2} - \gamma \|u\|^2_{L^2},$$

where \(\gamma = \max\{c(x): x \in U\}\). Let us assume that

$$\gamma = \max\{c(x): x \in U\} < \alpha C$$
where $C$ is the constant in the Poincare inequality. If $\gamma \leq 0$ then $B(u, u) \geq \alpha \|\nabla u\|_{L^2}^2$, and if $\gamma > 0$ then

$$B(u, u) \geq \alpha \|\nabla u\|_{L^2}^2 - \gamma \|u\|_{L^2}^2 > \left(\alpha - \frac{\gamma}{C}\right) \|\nabla u\|_{L^2}^2.$$  

Applying then Corollary 1 we obtain

$$B(u, u) \geq C_1 \|\nabla u\|_{L^2}^2 \geq C_2 \|u\|_{H^{1,2}}^2$$

where $C_1$ and $C_2$ are some positive constants. The latter inequality is called coercive condition.

Now, we notice that functions $|a_{ji}(x)|$ and $|c(x)|$ are continuous in $U$, hence they bounded there. Denoting by $M$ the common upper bound we find

$$B(u, u) \leq M \|u\|_{H^{1,2}}^2$$

for all $u \in C_0^\infty(U)$, and, consequently, for all $u \in H_0^{1,2}(U)$.

Summarizing, we conclude that $B(u, v)$ is a symmetric bilinear form satisfying the bilateral inequality

$$m \|u\|_{H^{1,2}}^2 \leq B(u, u) \leq M \|u\|_{H^{1,2}}^2 \quad (m, M > 0).$$

Let $|u|_B := \sqrt{B(u, u)}$. Then the new norm is equivalent to $\|u\|_{H^{1,2}}^2$ and we can again apply the Riesz theorem to show that for any bounded linear functional $F(v)$ there is a function $u \in H_0^{1,2}(U)$ such that equality (5) above holds. Thus we have obtained

**Theorem.** In the made assumptions, the weak solution of $Lu = 0$ exists and is uniquely defined.
